(Paper received 10 May 2001; accepted for publication 22 August 2001)

Levamisole is a broad-spectrum anthelminthic available for veterinary medical use for over 30 years. It shows activity against a wide variety of gastrointestinal and pulmonary nematodes (Thilenpont et al., 1966; Walley, 1966; Janssen, 1976), and possesses an immunomodulating effect (Renoux & Renoux, 1977; Symoens & Rosenthal, 1977).

Although the oral pharmacokinetics of levamisole has been extensively investigated in several animal species (Graziani & De Martin, 1977; Galtier et al., 1981, 1983; Bogan et al., 1982; Nielsen et al., 1983; Watson et al., 1988; McKellar et al., 1991; Garcia et al., 1994; Fernández et al., 1998) and in humans (Luyckx et al., 1982; Kouassi et al., 1986), there are only two studies regarding its disposition in goats after oral (p.o.) administration (Galtier et al., 1981; Chartier et al., 2000), and the pharmacokinetic parameters reported in both are scarce. The purpose of this study was to establish the bioavailability and other pharmacokinetic parameters of this drug following p.o. administration to goats, where pharmacokinetic data are currently extrapolated from those estimated in other ruminants, and it extends a previous work (Sahagún et al., 2000) where we studied the pharmacokinetics of levamisole after intravenous (i.v.) and subcutaneous (s.c.) administration.

The experiment was carried out in eight healthy male crossbred goats (aged 6 months, weighing 15–21 kg). They were acclimatized for 15 days before the experiments, and were maintained indoors on a diet of mixed hay and pelleted feed concentrate and had free access to fresh water. Protocols and procedures were approved by the Institutional Animal Care and Use Committee of the University of León.

Each goat was weighed the day before the experiment and administered a single oral dose of 7.5 mg/kg levamisole HCl (Sigma Chemical Company, St Louis, MO, USA). Levamisole was dissolved in 2.5 mL distilled water and given as an aqueous solution of about pH 4 using a gavage needle. After dosing, the gavage needle was flushed with 5 mL distilled water. Animals were fasted for 24 h and received their first folder 4 h after drug administration. Blood samples (5 mL) were collected into heparinized vacuum tubes (Venoject, Terumo Europe, Leuven, Belgium) by jugular venipuncture just prior to drug administration and at 5, 10, 20, 30, 40, 50, 60, 75, 90, 120, 150, 180, 210, 240, 300 and 360 min afterwards. Plasma was centrifuged, separated immediately and frozen at −20°C until assayed.

Plasma levamisole concentrations were determined by high-performance liquid chromatography (HPLC) with ultraviolet (UV) detection (213 nm) following a method previously developed (García et al., 1990) with minor modifications. The limit of detection was 0.016 μg/mL and mean extraction recovery of levamisole from plasma was 82.8%.

Compartmental and non-compartmental methods were used for each goat in the pharmacokinetic analyses. Compartmental analysis was performed using the nonlinear regression analysis program PCNONLIN (Metzler & Weiner, 1989), with a weighting factor of 1/C, and the initial estimates were determined by JANA (Dunne, 1985). The best fit was based on Akaike’s information criterion (Yamaoka et al., 1978a) and graphical analysis of weighted residuals. The other compartmental parameters were calculated by standard equations (Gibaldi & Perrier, 1982).

Non-compartmental parameters were calculated using expressions based on statistical moments theory (Yamaoka et al., 1978b; Gibaldi & Perrier, 1982). The plasma elimination rate constant (λ) was estimated by least squares regression of the logarithm of plasma concentration vs. time curve over the terminal elimination phase. The area under the plasma concentration–time curve (AUC) and the area under the first moment curve (AUMC) were calculated by the linear trapezoidal rule and extrapolated to infinity. The mean residence time (MRT) was defined as AUMC/AUC, and the mean absorption time (MAT) as the difference between MRT_p.o. and MRT_i.v., where MRT_p.o. and MRT_i.v. are the MRT of the drug after p.o. and i.v. administration, respectively. Total body clearance (Cl) was defined as dose/AUC, the volume of distribution at steady state (Vss) as MRT x Cl, and the apparent volume of distribution (Vd) as Cl/λ. The maximum plasma concentration (Cmax) and time of Cmax (tmax) were read directly from the concentration vs. time curve, and the oral absorbed fraction (F) was calculated as $F = \frac{AUC_{p.o.}}{AUC_{i.v.}} \times 100$. 

© 2001 Blackwell Science Ltd
where $AUC_{i.v.}$ and $AUC_{p.o.}$ are the $AUC$ after i.v. and p.o. administration, respectively.

All pharmacokinetic parameters were calculated for each animal and values are reported as mean ± standard deviation (SD). Differences between compartmental and non-compartmental data were determined by the paired t-test (Wayne, 1987) ($P \leq 0.05$). This test was also used to assess differences between oral data and those obtained after i.v. administration (Sahagún et al., 2000).

Plasma concentration–time profiles following 7.5 mg/kg oral administration (Fig. 1) were best described by a two-compartment open model. Levamisole was detected in plasma for up to 6 h post-administration. Compartmental and non-compartmental pharmacokinetic parameters are summarized in Tables 1 and 2, respectively.

Levamisole plasma concentration decreased rapidly, with a mean half-life ($t_{1/2b}$) of $86.57 \pm 24.62$ min. The mean $AUC$ was $74.30 \pm 15.23$ µg min/mL; $V_{ss}$, $7.867 \pm 1.789$ L/kg and $Cl$, $105.3 \pm 24.76$ mL/kg/min. The pharmacokinetic parameters describing the rate and extent of absorption exhibited mean values of $0.0515 \pm 0.0145$ min$^{-1}$ for $k_a$, $0.703 \pm 0.123$ µg/mL for $C_{max}$ and $29.49 \pm 6.31$ min for $t_{max}$, whereas $F$ was $63.22 \pm 6.34$%.

The paired t-test revealed significant differences between compartmental and non-compartmental values for $V_{ss}$, $C_{max}$, $t_{max}$ and $F$. Significant differences were also found for $AUC$ and $Cl$ when both i.v. and oral routes were compared.

Levamisole plasma concentrations vs. time data after p.o. administration were best described by a two-compartment open model, which is in agreement with previous studies reported in goats (Galtier et al., 1981) and sheep (Galtier et al., 1981; Fernández et al., 1998). By contrast, pigs (Galtier et al., 1983) and dogs (Watson et al., 1988) followed a one-compartment open model, whereas in humans (Luyckx et al., 1982; Kouassi et al., 1986) and rabbits (García et al., 1994) both models have been utilized. In previous work (Sahagún et al., 2000), levamisole was also described in goats by a two-compartment open model after i.v. and s.c. administration.

Neither the oral disposition rate constant $\beta$ nor its $t_{1/2\beta}$ showed significant differences with the values determined after i.v. administration (Sahagún et al., 2000). Beta (β) was twofold higher than that determined after p.o. administration in goats and sheep by Galtier et al. (1981), and in pigs by Galtier et al. (1983). The relatively fast elimination of the drug from the body would reduce the presence of residues in goat tissues. The oral clearance rate (Cl) was also higher than values previously reported in goats (Galtier et al., 1981), sheep (Galtier et al., 1981) and humans (Luyckx et al., 1982; Kouassi et al., 1986).

On the other hand, $k_a$ showed a moderately rapid absorption from the gastrointestinal tract, with a mean value 12-fold lower than in sheep and four-fold lower than in goats and pigs (Galtier et al., 1981, 1983), similar to those reported in humans (Luyckx et al., 1982), rabbits (García et al., 1994) and sheep (Fernández et al., 1998), and somewhat higher than those described in humans by Kouassi et al. (1986) and in dogs (Watson et al., 1988).

The maximum plasma concentration ($C_{max}$) was similar to those previously found in the same animal species (Galtier et al., 1981) with a higher dose (10 mg/kg), and in sheep (Bogan et al., 1982; McKellar et al., 1991) and cattle (Nielsen et al., 1983) with the same oral dose (7.5 mg/kg). However, Chartier et al. (2000) in parasitized goats (12 mg/kg), and Galtier et al. (1981) (10 mg/kg) and Fernández et al. (1998) (7.5 mg/kg) in sheep obtained values higher than that of ours.

Levamisole was absorbed more slowly in the present study, with a $t_{max}$ of 29.49 min, compared with 10 min indicated by

*Significantly different from compartmental parameters (paired t-test, at P ≤ 0.05).

Galtier et al. (1981) and Chartier et al. (2000) in goats or with 5 min determined by Galtier et al. (1981) in sheep. Other authors obtained higher values in sheep (Bogan et al., 1982; Fernández et al., 1998), cattle (Nielsen et al., 1983), dogs (Watson et al., 1988) and rabbits (García et al., 1994) than those described by us.

The reported differences on kinetic behaviour could be attributed to differences in experimental conditions, sex, inter- or intraspecies variations, the presence of nematodes or to the different preparations used. For example, Galtier et al. (1981) and Chartier et al. (2000) administered commercial formulations to female goats only.

The absorbed fraction was about 66%, suggesting that levamisole was relatively well absorbed by this route. There is no data on oral bioavailability in goats, but this is consistent with the results obtained after p.o. administration in sheep (Fernández et al., 1998), pigs (Galtier et al., 1983), dogs (Watson et al., 1988), rabbits (García et al., 1994) and humans (Luyckx et al., 1982; Kouassi et al., 1986). A higher bioavailability is achieved by s.c. route (78%) (Sahagún et al., 2000). Thus, it would be expected that s.c. administration provides better efficacy than p.o. administration against lungworms.

Although caution should be maintained when this anthelmintic is administered to goats (Smith & Bell, 1971), a narrow therapeutic index has not been shown for levamisole in this animal species. While adverse effects such as hyporexceptibility, deep respiratory movements, stasis and muscle tremors after levamisole i.v. administration (Sahagún et al., 2000) and tremors and hyperesthesia in i.m. route (Galtier et al., 1981) have been reported in goats, there are no data on toxicosis concerning s.c. administration. On the other hand, only mild signs of transitory intoxication have been described in goats with an oral dose of 16 mg/kg, and no adverse reactions have been seen at oral dose levels of 12 mg/kg (Babish et al., 1990; Chartier et al., 2000) and with a dose of 7.5 mg/kg in this study or in Galtier et al. (1981) (10 mg/kg).

Understanding of the pharmacokinetic behaviour of anthelminthic drugs can contribute to improve parasite control in livestock. From the relatively high bioavailability observed in the current study, we recommend the oral route as an effective way to administer levamisole in goats for treating gastrointestinal nematodes.

ACKNOWLEDGMENTS

Financial support for the present study was obtained from the Junta de Castilla y León, grant no. 43/96.
